Product Requirements Document

Service Operations Exception Triage

Portfolio product concept | Version 1.3 | November 2026 | Draft for discovery

PRODUCT GOAL: Help operations teams spot and triage service exceptions faster while preserving human decision authority.

Problem and target users

Operations teams coordinating work orders must balance due windows, regional demand, capacity, and changing information. Static reports may show volume without making exceptions requiring immediate review obvious. The concept is a human-in-the-loop queue for dispatchers/coordinators (find exceptions and understand why flagged), operations leads (see capacity pressure), and service managers (maintain accountability).

Evidence note: This portfolio concept is informed by prior work-order and operational analytics experience. The requirements below are a product translation of that problem space; prototype records are synthetic.

Workflow and scope

1. Read approved work-order status, due window, region, capacity, and dependency signals.
2. Flag possible exceptions with a plain-language reason and source timestamp.
3. Let users inspect evidence and linked work orders before acting.
4. Allow an explicit human decision: mark reviewed, defer with reason, or route for follow-up.
5. In a production system, log reviewer, action, time, rationale, and outcome.

Non-goals: automatic dispatch/reassignment; replacing the system of record; unsupported predictive claims; irreversible updates without confirmation.

Prioritized requirements and acceptance criteria

Priority	Requirement	Acceptance criteria
P0	Exception queue	Each row shows exception, region, priority, reason, and relevant due/capacity context.
P0	Inspectable evidence	User can see triggering signal, source, and timestamp before acting.
P0	Human control	No assignment/system update occurs without explicit user action and confirmation.
P1	Severity filters	Queue displays matching rows and visible result count.
P1	Review disposition	Production version records reviewer, action, timestamp, and defer/override rationale.
P2	Regional/time trends	Authorized users compare exception volume and resolution time by period.

Success metrics and guardrails

Primary: median time to first meaningful triage action; prioritization accuracy against a reviewed reference set; share of exceptions triaged within the required window. Guardrails: missed high-severity exceptions, false-positive rate, reopened/deferred items, override rate, stale data exposure, and actions without sufficient evidence. Set baselines and targets after measuring the current workflow; no impact result is claimed for this concept.

Discovery and validation plan

Prior workflow-testing experience across the related American Express and Powerhouse workstreams included alpha testing with 50 internal participants and nearly 200 users across UAT, task-based usability testing, and observation combined. These are aggregate figures across both workstreams, not per-company counts, and do not represent validation of this PRD concept. For this concept, next-step validation should recruit dispatchers and operations leads, map current handoffs and escalation rules, and test a prototype with non-sensitive scenarios. Measure time-to-triage, prioritization accuracy, error detection, and whether users can explain why a record was flagged; iterate based on observed errors.

Open questions

Which system is the source of truth? Who defines severity? What data latency or missingness makes recommendations unsafe? Which exceptions require escalation? Which access controls, audit requirements, and integrations are mandatory?

Prototype note: The companion web demo uses illustrative synthetic records and local-only review state. It is not connected to an operational system. Alpha/UAT/usability-testing participant figures above refer to prior workflow-testing activities, not validation of this prototype.
